sailani@stanford.edu

- **Introduction**
- **Our Current state of research**
- **An overview of two whole exome sequencing studies of mendelian diseases.**

Case#1: Alopecia and Mental Retardation (APMR) Syndrome

Case#2: Pseudorheumatoid Dysplasia

- **Concluding remarks**

Current Research:

Our laboratory develops and uses a variety of approaches to analyze genomes, other omes, and regulatory networks. We apply these approaches to understand human variation and health.

<http://snyderlab.stanford.edu/index.html>

We are presently in an omics revolution in which genomes and other omes can be readily characterized. Our laboratory develops and uses a variety of approaches to analyze genomes, other omes, and regulatory networks. We apply these approaches to understand human variation and health.

Alopecia And Mental Retardation (APMR) Syndrome

- A very rare autosomal recessive condition
- Only a few families have been reported; most in the context of consanguinity.
- Affected individuals manifest with loss of hair on the scalp, the absence of eyebrows and eyelashes, and variable intellectual disability.
- However, there is high genetic heterogeneity in APMR cases as none of the families reported before shared the same aberrant locus associated with the disease.
- Linkage analyses in the past have identified three regions that are associated with APMR.

Alopecia And Mental Retardation (APMR) Syndrome

These previous studies were based on linkage analyses and were able to identify regions of interest, but no specific causative genes or variants.

We employed whole-exome sequencing to identify the underlying genetic variant(s) associated with APMR syndrome in a large consanguineous family.

Methods:

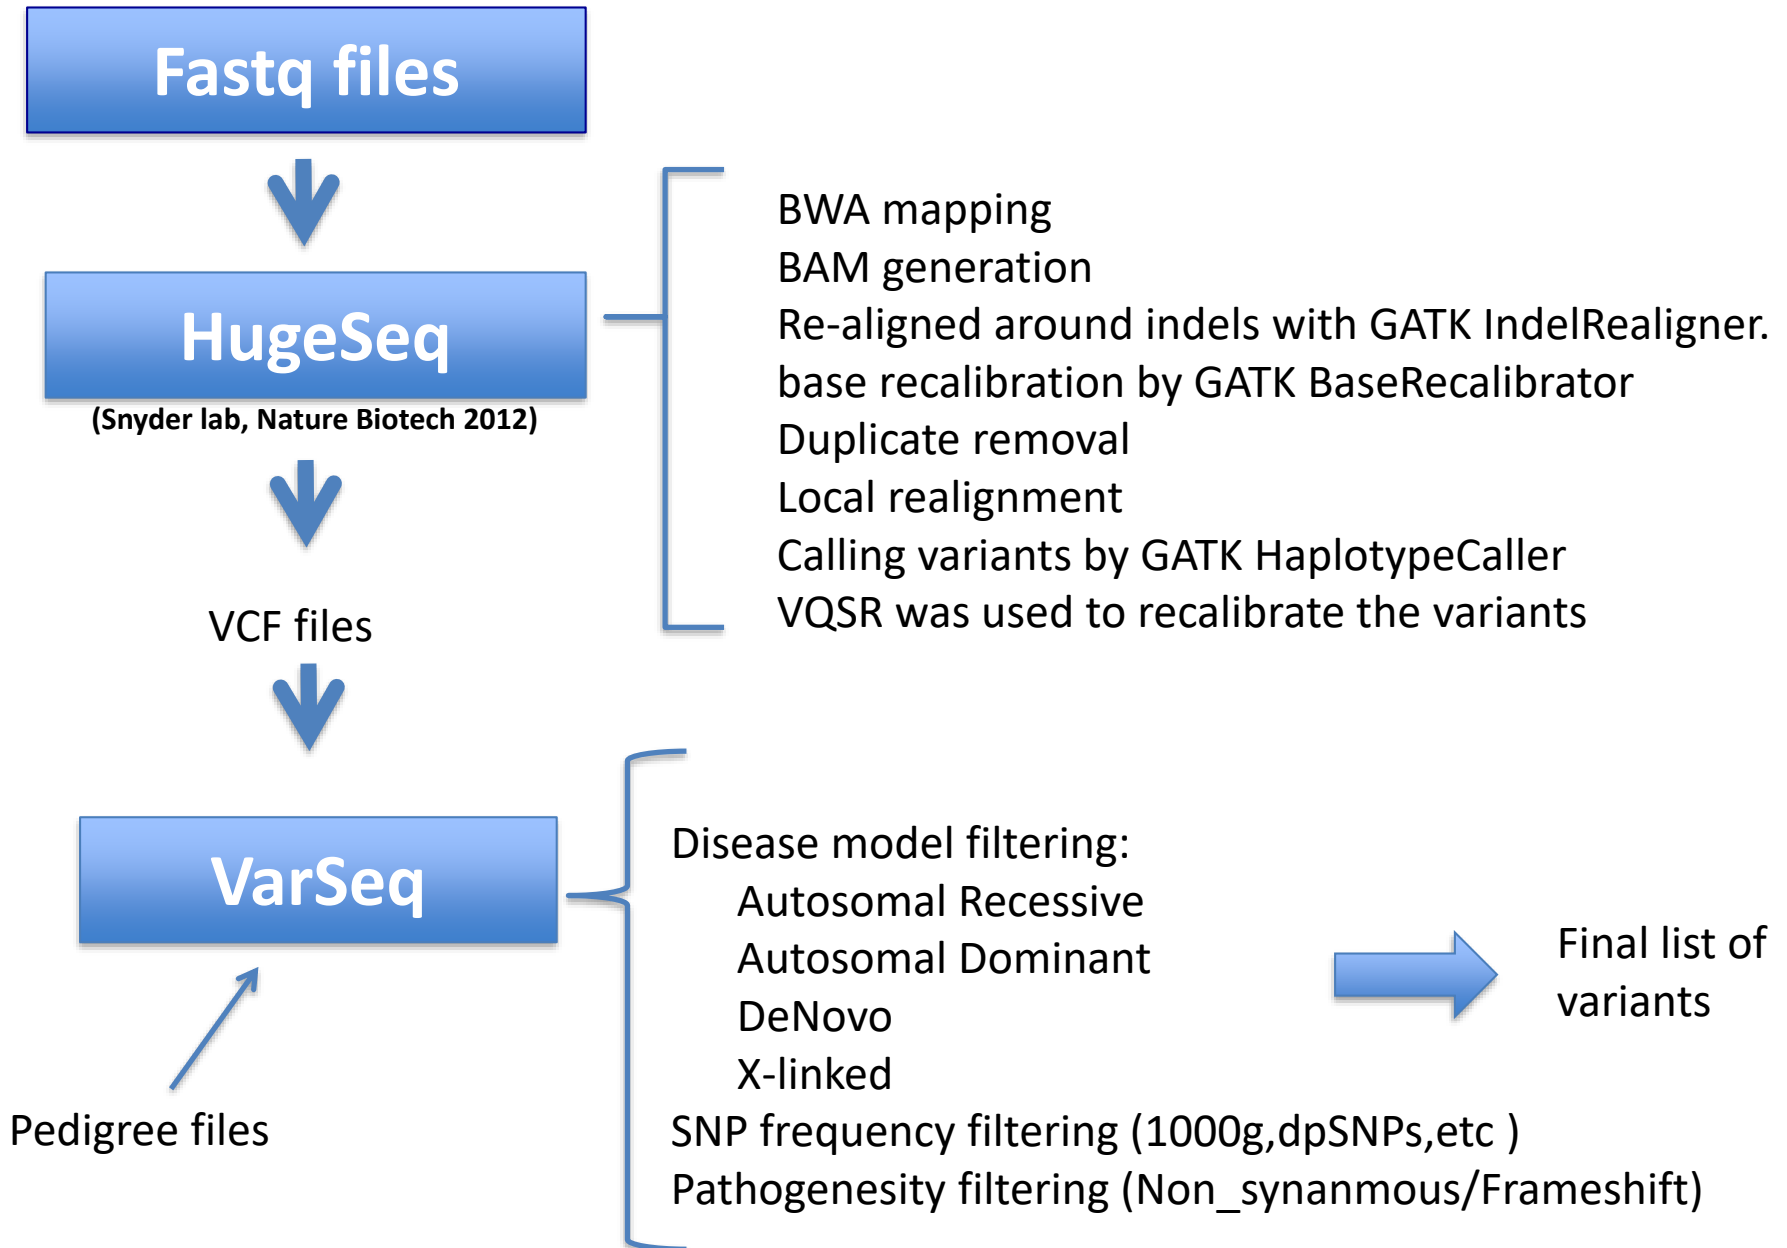

Capture Kit: Agilent SureSelectXT HumanAllExon V5

Four libraries per one lane of HiSeq2500

Hugeseq and BINA pipeline

VarSeq for variant filtering

Variant Calling Pipeline

VarSeq filtering Steps:

As an **autosomal recessive mode of inheritance** is indicated both by the pattern of segregation of APMR syndrome in this family and in previous reported families, we began by searching for **homozygous variants**.

We selected variants with minor allele frequency (MAF) less than 0.01 in public databases:

- dbSNP Common 144 (Database of Single Nucleotide Polymorphism, NCBI).
- 1000 Genome project phase 3 (<http://www.1000genomes.org>).
- Exome Aggregation Consortium (ExAC).
- Exome Variant Server-NHLBI GO Exome Sequencing Project (ESP), Seattle, WA (<http://evs.gs.washington.edu/EVS/>).

VarSeq filtering Steps:

Runs of Homozygosity and AHSR location on chromosome 3.

ROH are long stretches of consecutive homozygous genotypes reflecting segments shared identically by descent (Broman and Weber 1999) and known to harbor mutations for recessive diseases.

ROH were estimated by H3M2 algorithm (Magi et al. 2014).

AHSG resides within a 17 Mb linkage region previously reported to be associated with APMR (APMR1)

Alopecia-mental retardation syndrome 1 (APMR1)

Localization of a novel locus for alopecia with mental retardation syndrome to chromosome 3q26.33–q27.3

The amino acid sequence of AHSG colored according to the conservation scores.

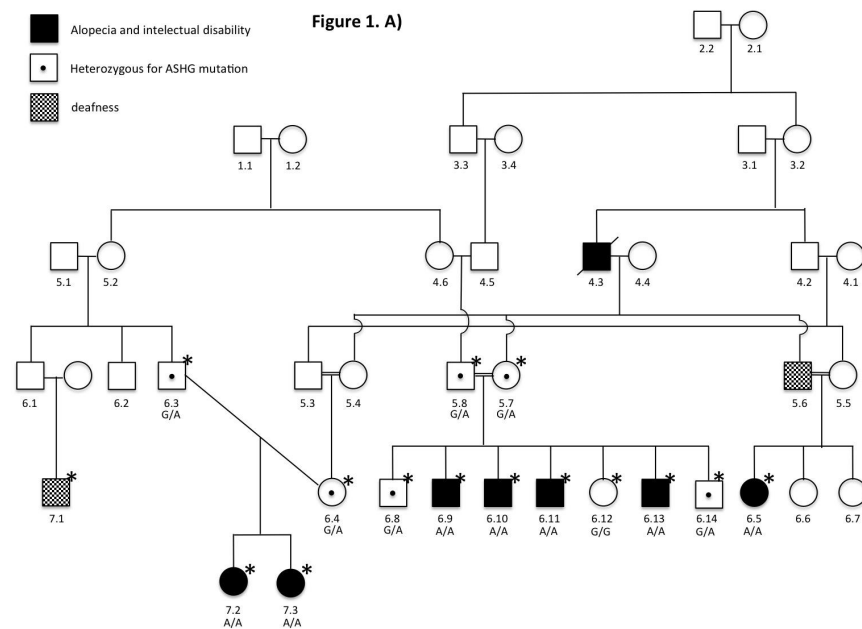

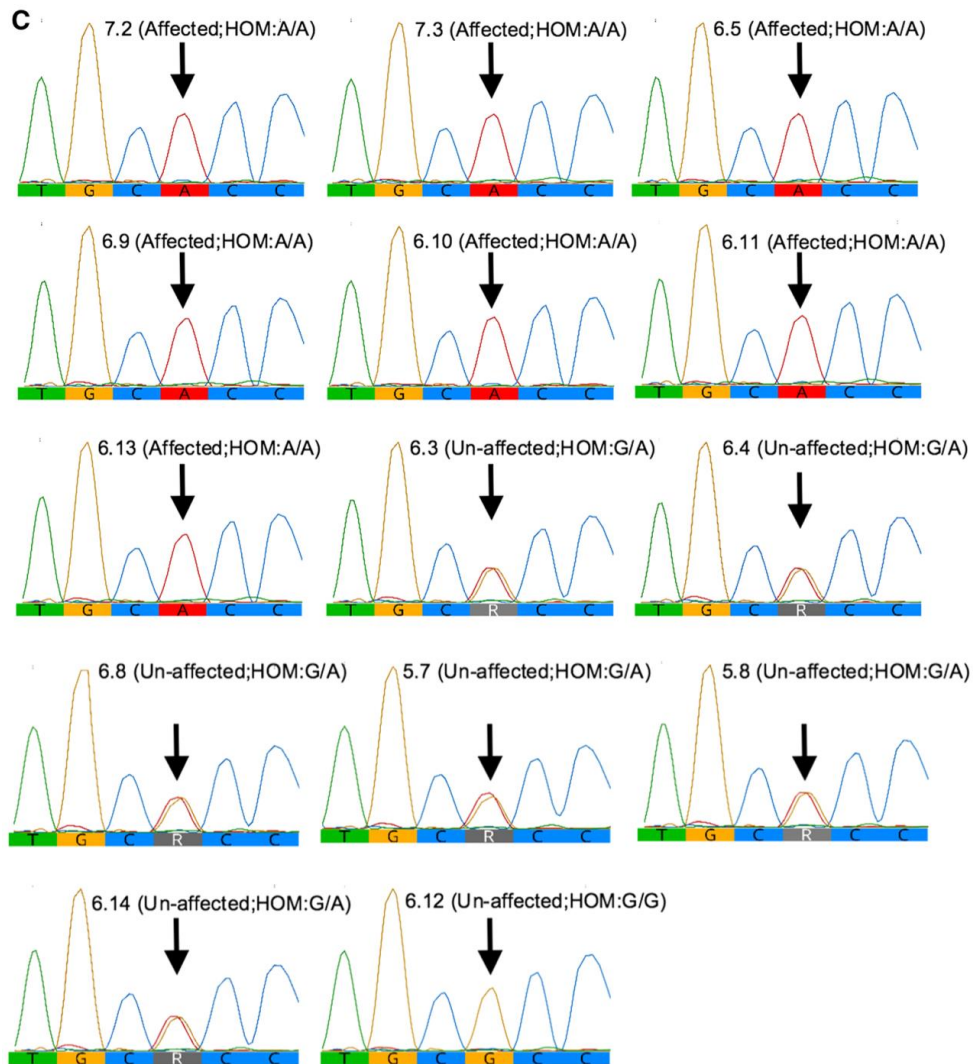

The conservation scale:

- e** - An exposed residue according to the neural-network algorithm.
- b** - A buried residue according to the neural-network algorithm.
- f** - A predicted functional residue (highly conserved and exposed).
- s** - A predicted structural residue (highly conserved and buried).
- X** - Insufficient data - the calculation for this site was performed on less than 10% of the sequences.

p.Arg317His occurs in a predicted functional residue, highly conserved and exposed (generated by ConSurf method).

We confirmed the homozygosity of this variant by Sanger sequencing

Post-translational modifications (PTMs) are common in AHSN protein

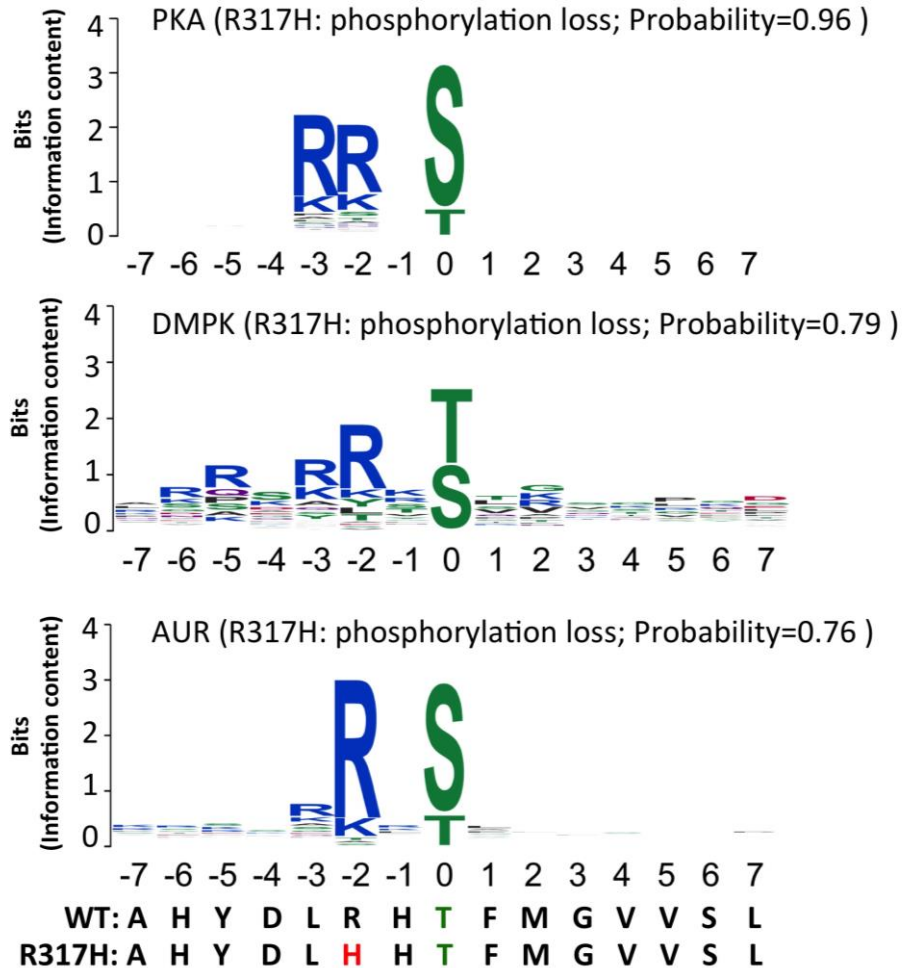

The identified variant is predicted to affect the pro-peptide

Immune-precipitating AHSN from serum followed by SDS polyacrylamide gel electrophoresis

Arg317His disrupts a phosphorylation motif

p.Arg317His disrupts this phosphorylation motif, potentially leading to a loss of phosphorylation at p.Thr319.

We used MIMP algorithm to evaluate the potential impact of p.Arg317His on this motif.

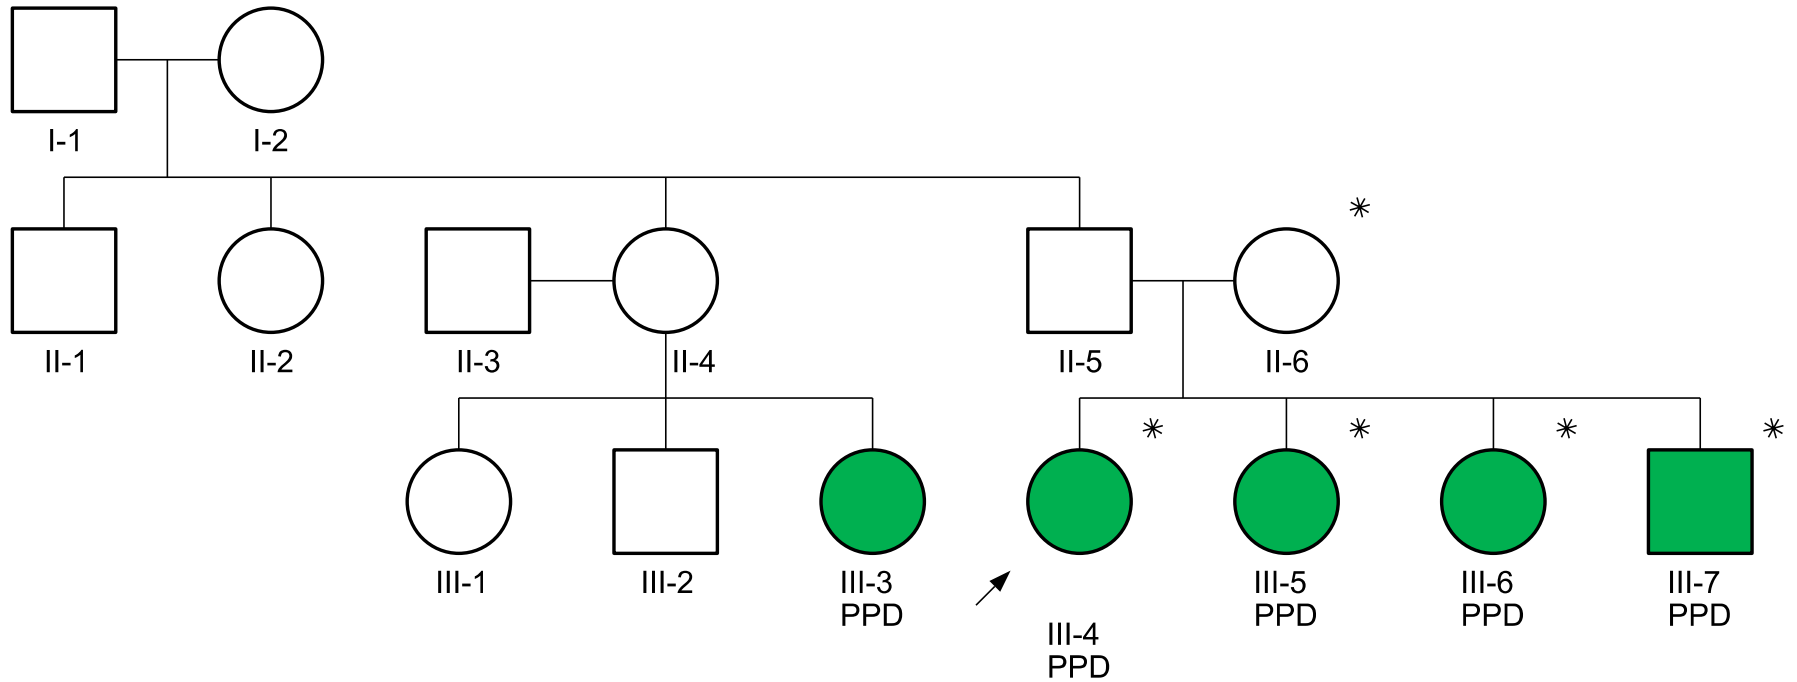

- **AHSG as a phosphorylated glycoprotein is a multifunctional extracellular calcium-regulatory protein.**
- **Is an important participant of diverse normal and pathological processes, including production of growth hormone (GH), nerve growth factor (NGF), transforming growth factor II (TGFb).**
- **Promotes primary keratinocyte migration.**
- **Is particularly abundant at sites where basal keratinocytes are reorganizing to form hair follicle placodes.**

**We therefore suggest AHSG gene as a potential
Candidate for APMR in this family.**

Case #2

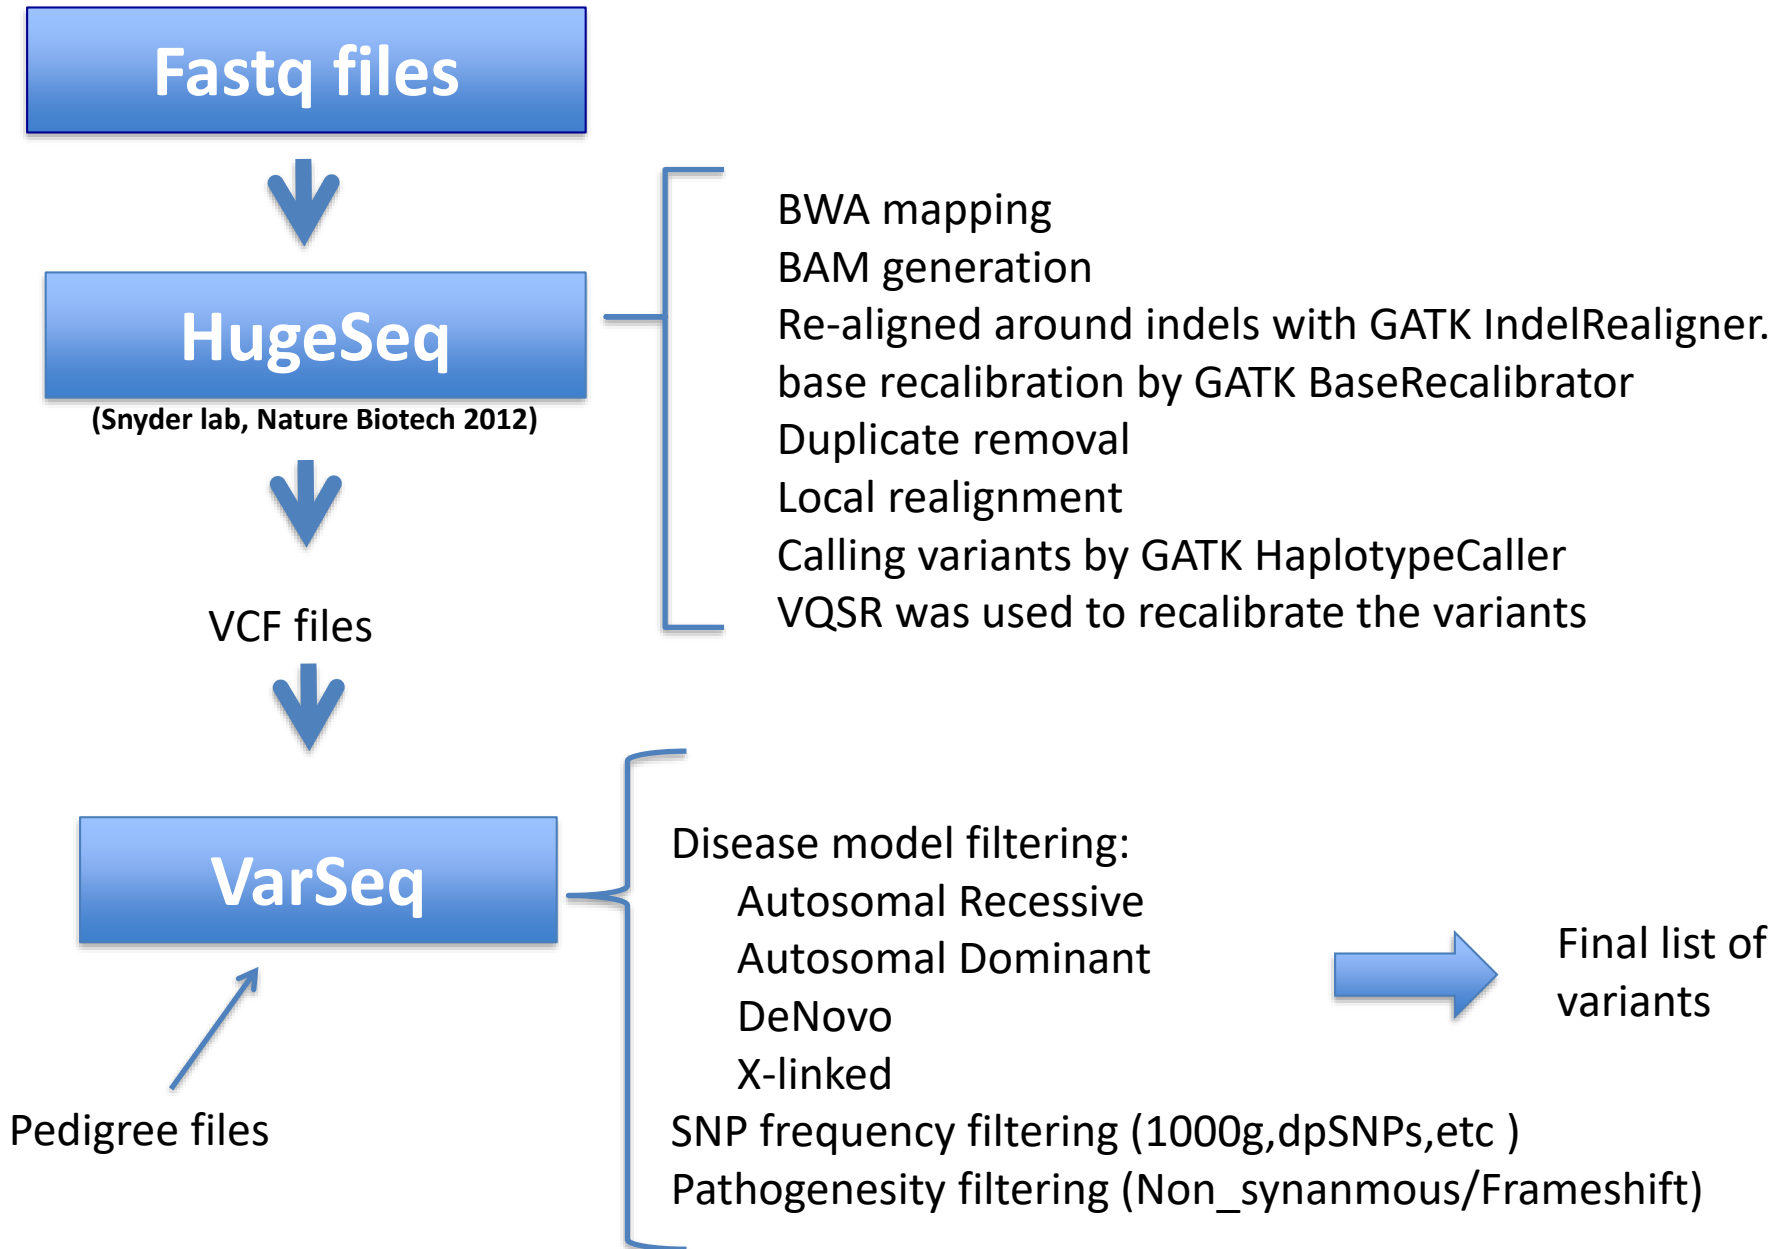

WISP3 mutation associated with Pseudorheumatoid Dysplasia

Here we report genetic characterization of a family segregating an uncharacterized form of skeletal dysplasia.

The patients were asymptomatic at birth, with normal growth, development and intelligence as well as no facial, joint, and skeletal system deformity. However, the disease started to manifest at four to six years of age in affected individuals and progressively worsened.

Variant Calling Pipeline

VarSeq filtering Steps:

As an **autosomal recessive mode of inheritance** is indicated by the pattern of segregation of disease in this family, we began by searching for **homozygous variants**.

We selected variants with minor allele frequency (MAF) less than 0.01 in public databases:

- dbSNP Common 144 (Database of Single Nucleotide Polymorphism, NCBI),
- 1000 Genome project phase 3 (<http://www.1000genomes.org>),
- Exome Aggregation Consortium version (ExAC)
- Exome Variant Server-NHLBI GO Exome Sequencing Project (ESP), Seattle, WA (<http://evs.gs.washington.edu/EVS/>),

VarSeq filtering Steps:

We confirmed the homozygosity of this variant by Sanger sequencing and showed that the variant segregates in the family

Loss-of-function mutations in the *WISP3* gene has been associated with Progressive pseudorheumatoid dysplasia (PPD)

In 1998, linkage studies in consanguineous families segregating PPD (El-Shanti et al, 1998; Fischer, J. et al 1998) mapped the candidate region on a 3-cM interval on chromosome 6q22.

One year later, Hurvitz et al 1999 showed that mutations in the *WISP3* gene that fall within the linkage region are the strongest candidate to cause this autosomal recessive condition (Hurvitz et al 1999).

letter

Mutations in the CCN gene family member *WISP3* cause progressive pseudorheumatoid dysplasia

Jennifer R. Hurvitz¹, Wafaa M. Suwairi^{1,2,3}, Wim Van Hul⁴, Hatem El-Shanti⁵, Andrea Superti-Furga⁶, Jean Roudier⁷, Daniel Holderbaum⁸, Richard M. Pauli⁹, J. Kenneth Herd¹⁰, Els Van Hul⁴, Hossien Rezai-Delui¹¹, Eric Legius¹², Martine Le Merrer¹³, Jamil Al-Alami¹⁴, Sultan A. Bahabri³ & Matthew L. Warman¹

Progressive pseudorheumatoid dysplasia (PPD):

A rare skeletal dysplasia characterized by predominant involvement of articular cartilage with progressive joint stiffness.

is an autosomal recessive genetic disease.

PPD remains a diagnostic challenge because of the rarity of the disease and the heterogeneity in the phenotypes, as well as having similarities with other disorders.

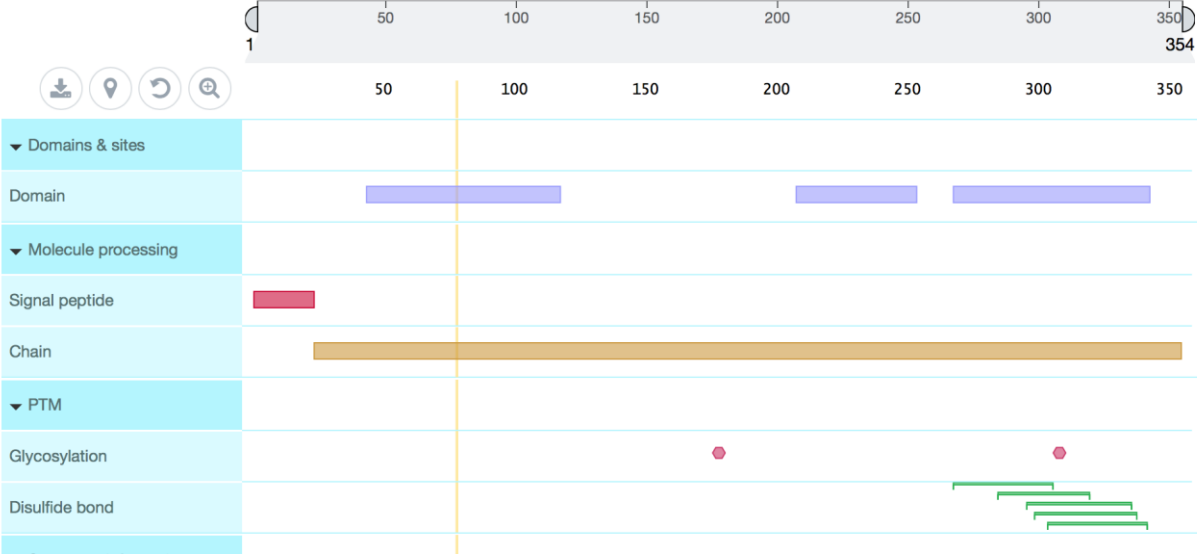

PPD is caused by Wnt1-inducible signaling protein 3 (WISP3) mutations.

Clinical and radiographic findings in a 13-year-old male PPD patient

WISP3 encodes Wnt1-inducible signaling protein 3, a cysteine-rich, multidomain, secreted protein

WISP3:c.210C>A p.Cys70* occurs in IGFBP N-terminal domain

The variant identified in this study at p.Cys70* would, if not subjected to nonsense mediated mRNA decay, produce a significantly truncated protein that misses major part of the protein making it unlikely that normal protein function would be retained.

Conclusion:

Combining our whole exome sequencing data with clinical documentation (familial histories, genetic data, clinical and radiological findings), we have diagnosed the families with Progressive Pseudorheumatoid Dysplasia (PPD).
